Acca Esimus Full Registration.rarA histological and histomorphometric study on coxofemoral luxation in horses. A detailed histological and histomorphometric study was performed on 12 embryonic, 11 foetal, and 16 adult femurs; as well as on all aspects of the coxofemoral joint of six fetuses and eight ponies with full-thickness coxofemoral luxations. A high frequency of imperfect closure of the coxofemoral joint in foetal and adult stifles, and of the great trochanter in adult stifles indicates the importance of this joint for animal locomotion. Since stifle joints were not opened or closed in the course of normal growth, the animal's normal foetal locomotor pattern is preserved by means of a steady state histological condition in most stifle joints. Stifle joints that open and close in early foetal life will have a higher frequency of subchondral insufficiency fracture, whereas those that remain closed will have a higher proportion of articular chondrolysis. The frequency of coxofemoral luxation is greater in foetal and adult ponies than in horses; in both species, the osteoarthritic lesions most frequently involve the lateral trochlear ridge of the femoral condyle, the lateral trochlear ridge of the tibial plateau, and the anterior aspect of the tibial plateau.
